ABSTRACT

Background: Methicillin-resistant Staphylococcus aureus (MRSA) is an established pathogen in most health care facilities. MRSA strains are also important for their resistance to many other commonly used antibiotics.

Objectives: To find out prevalence of MRSA strains and coproduction of β-lactamase and antibiotic sensitivity pattern of these strains.

Materials and Methods: During the period of September 2009 to December 2010, a total of 200 strains of S. aureus were isolated from various specimens of different patients attending and admitted at C. U. Shah Medical College and Hospital, Surendranagar, Gujarat. Standard procedures were followed for isolation and identification of S. aureus isolates. Antibiotic susceptibility testing and detection of MRSA was done by Kirby Bauer disk diffusion method, as per Clinical and Laboratory Standards Institute (CLSI) guidelines. The production of β-lactamase was studied by the rapid method using nitrocefin disk.

Results: Among 200 isolates of S. aureus, 117 (58.5 %) were methicillin-resistant, of which 110 (94.02%) were found to be multidrug-resistant. Among 117 MRSA strains, 86.59 % were resistant to ciprofloxacin, 81.71% were resistant to cephalexin, 80.49% were resistant to cefaclor and 79.27% were resistant to erythromycin. Vancomycin was the most effective drug as all MRSA isolates were sensitive to it. 93.90% MRSA isolates were sensitive to linezolid and 91.46% were sensitive to teicoplanin. 82.91% MRSA isolates were also co-producers of β-lactamase.

Conclusions: The high incidence of MRSA in this hospital warrants for the judicial use of antibiotics and application of infection control measures to avoid therapeutic crisis resulting from multidrug-resistant MRSA.

Key Words: MRSA, Staph aureus, Rural Gujarat

INTRODUCTION

Staphylococcus aureus is one of the most common human pathogens and is capable of causing a wide range of infections ranging from localized skin infections to fatal systemic infections. It is a common cause of hospital and community acquired infections worldwide.

The incidence of community-acquired and hospital-acquired S. aureus infections has been rising with increasing emergence of drug-resistant strains called methicillin-resistant S. aureus (MRSA) [1]. MRSA strain has been progressively causing increased mortality, morbidity, and health care costs with skin and soft tissue infections, ventilator-associated pneumonia, catheter associated bacteremia, and many other infections in hospitals and community.

Historically, resistance to penicillinase-stable penicillins such as methicillin, oxacillin, nafcillin and cloxacillin has been referred to “methicillin resistance” [2]. This resistance is primarily due to the presence of an unusual penicillin binding protein (PBP2a) in the bacterial cell wall and has a low binding affinity for β-lactam antibiotics. PBP2a is encoded by the mecA gene located on the staphylococcal chromosome.
cassette mec. MRSA infection is difficult to treat, because many MRSA strains are also resistant to multiple other antimicrobial drugs [3].

The present study identifies the prevalence of multidrug resistant MRSA strains and investigates their antibiotic sensitivity pattern in C. U. Shah medical College & Hospital, Surendranagar, Gujarat.

MATERIAL AND METHODS

**Study duration:** The present study was conducted at the Department of Microbiology of C. U. Shah Medical College & Hospital, Surendranagar, Gujarat from September 2009 to December 2010.

**Sample size:** A total of 200 strains of S. aureus were isolated from various clinical specimens at C. U. Shah Medical College and Hospital, Surendranagar, Gujarat.

**Isolation and Identification:** All specimens were inoculated on blood agar and MacConkey agar (HiMedia, New Delhi, India). Inoculated plates were incubated at 35°C. After overnight incubation, suspected S. aureus colonies were confirmed by gram staining, catalase test and coagulase (slide & tube) tests, which were performed as per standard guidelines [4].

**Screen test for MRSA:** Disk diffusion method was performed as per Clinical and Laboratory Standards Institute (CLSI) guidelines. A peptone water suspension equivalent to 0.5 McFarland standard was prepared from isolated colonies. A swab was dipped in suspension and streaked over surface of a Mueller-Hinton agar. Cefoxitin (30 µg) disk was applied to the surface of inoculated plate and incubated at 33°C for 18 hours. S. aureus isolates with zone diameter ≤ 21 mm were reported as MRSA [2].

**Screen test for inducible clindamycin resistance:** Disk approximation test as per Clinical and Laboratory Standards Institute (CLSI) guidelines was performed by placing a 2 µg clindamycin disk from 15 to 26 mm away from the edge of a 15 µg erythromycin diskover surface of a inoculated Mueller-Hinton agar. Following overnight incubation at 35°C, organism that shows flattening of the clindamycin zone adjacent to erythromycin disk (referred to as ‘D zone’) indicate inducible clindamycin resistance [2] as shown in Figure-1.

**Antibiogram of MRSA isolates:** A suspension equivalent to 0.5 McFarland standard was prepared from single isolated colonies. A swab was dipped in suspension and streaked over surface of a Mueller-Hinton agar. Antibiotic disks of linezolid (30 µg), vancomycin (30 µg), teicoplanin (30 µg), tetracycline (30 µg), doxycycline (30 µg), gentamycin (10 µg), trimethoprim-sulfamethaxasole (1.25/23.75 µg), ciprofloxacin (5 µg), levofloxacin (5 µg), ampicillin-sulbactum (10/10 µg), penicillin (10 U), amoxicillin, cefaclor (30 µg), erythromycin (15 µg), and clindamycin (2 µg) were used. The disk contents and zones of inhibition were as per the recommendation of the CLSI [2].

**Ethical clearance:** The study was approved by Institutional Ethics Committee (Human).
RESULT

Among 200 isolates of S. aureus, 117 (58.5%) were methicillin-resistant S. aureus (MRSA). Most number

Table 1: Prevalence of MRSA

Prevalence of inducible clindamycin resistance among MRSA isolates was 5.21% (6 out of 117) & 1.20% (1 out of 83) among MSSA isolates as shown in Table 2. Out of 117 MRSA strains, 97 (82.91%) were co-producers of β-lactamase.

Table 2: Inducible clindamycin resistance

Out of 117 MRSA strains, 97 (82.91%) were co-producers of β-lactamase. MRSA strains which were resistant to three or more than three antibiotics tested were considered to be multidrug-resistant MRSA. Out of 117 MRSA isolates, 110 (94.02%) were multidrug resistant as shown in Table 3. Among 117 MRSA strains, 86.59% were resistant to ciprofloxacin, 81.71% were resistant to cefalexin, 80.49% were resistant to cefaclor and 79.27% were resistant to erythromycin.

Table 3: Antiibiogram of MRSA isolates

All 100% MRSA isolates were sensitive to vancomycin, 93.90% were sensitive to linezolid and 92.68% were sensitive to teicoplanin as shown in Table 3.

DISCUSSION

Various studies show that the epidemiology of MRSA over different parts of India is variable. Present study shows prevalence of MRSA of 58.9% which is higher than most other studies, as shown in Table 4. The variation is probably due to differential clonal expansion and drug pressure in community.

Multidrug resistance is a common feature of MRSA [8]. Among isolates of present study, 110 (94.02%) were multidrug resistance. It is higher as compared to other studies such as 72.1% in Tiwari et al [9], 63.6% in Rajaduraipandi et al [6], 32% by Anupurva et al [10] and 67.8% in Styers et al [11]. Still all isolates were sensitive to vancomycin, 93.90% were sensitive to linezolid and 91.46% were sensitive to teicoplanin. Among drugs other than β-lactams, high resistance was found against ciprofloxacin (86.59%), erythromycin (79.27%), levofloxacin (67.07%) and cotrimoxazole (65.85%).

In present study, prevalence of inducible clindamycin resistance among MRSA isolates was 6 out of 117 (4.88%), while among MSSA isolates it was 1 out of 83 (1.20%). Thus prevalence of inducible clindamycin resistance is higher in MRSA isolates. This was in concordance with a few of the studies reported like - Yilmaz G et al [12]. Clindamycin can be used as an oral agent for treatment of uncomplicated infections of MRSA were isolated from cutaneous and wound specimens (51.22%) followed by urine, sputum & blood, as shown in Table 1.
with MRSA. But inducible clindamycin strains if falsely reported as susceptible can lead to therapeutic failure.

MRSA is primarily due to the presence of an unusual penicillin binding protein (PBP2a) in the bacterial cell wall having a low binding affinity for β-lactams. Production of β-lactamase is another mechanism of resistance commonly found in *S. aureus*. In present study, 97 (82.91%) MRSA isolates were also producers of β-lactamase. This was in concordance with a few of the studies reported like - Haq et al [13].

MRSA spreads rapidly by hands of medical personnel within hospital environment. Multiple & prolonged use of antibiotics and prolonged hospitalization are other important factors which make hospital an ideal place of transmission and perpetuation of MRSA. Preventing colonisation and infection remains the most effective way to control the spread of MRSA and simple measures such as patient isolation, cohorting doctors and nurses working with patients. Strict enforcement of hand washing is the most effective way to reduce the spread of this pathogen in the hospital.

**CONCLUSION**

The results of the present study show a high prevalence of MRSA at this hospital. The treatment options for MRSA strains have been restricted to potentially toxic antimicrobials like vancomycin, clindamycin. This poses a serious problem for antibiotic therapy of *S. aureus* infections and leads to high morbidity and mortality.

Therefore, there is no other way than to stop inappropriate use of antibiotics, to constantly conduct microbiological surveillance like this, and follow infection control measures like hand washing and other aseptic techniques to avoid therapeutic crisis resulting from multidrug resistant MRSA. Also it is necessary to conduct periodic screening of hospital staff for nasal carriage of MRSA at a regular basis followed by the treatment of the identified carriers.
