ABSTRACT
Background: Colorectal cancer (CRC) is one of the prevalent diseases that can be diagnosed timely using appropriate screening programs. This study aimed to review the predictive factors for participation in colorectal cancer screening.
Methods: International databases including PubMed, ISI and Scopus were considered for search of English articles by 30 December, 2018. Thirty-one published articles were finally entered into the study. Keywords were “colorectal cancer”, “colorectal neoplasm”, “predictor”, “screening”, “Fecal Occult Blood Test (FOBT)”, “Fecal Immunochemical Test (FIT)”, “education”, “smoking”, “obesity” or a combination of them in the title/abstracts.
Findings: There were 367,248 subjects reviewed in this systematic review of 31 published articles consisted of two cohorts, one quasi-experimental; one mixed method, three randomized trial and twenty-six cross-sectional design.
Conclusion: According to the results, knowledge, income, being married and female, trust to physician and kindly contact of health providers, counselling centres disorders were the main predictive factors for participation in the CRC screening programs.

Key words: Colorectal cancer, Colorectal neoplasm, Predictor, Screening, FOBT, FIT

INTRODUCTION
Cancer is one of the prevalent diseases that account for a large volume of lethal consequences as well as care efforts [1-5]. Among them, Colorectal Cancer (CRC) is now responsible for a large part of the burden of cancer and the fourth leading cause of cancer death worldwide [6]. The CRC is the second most common cancer in women [7,8] and after breast cancer is the most common cause of death in women [9,10]. Meanwhile, it can also be considered as the third most common cancer in men worldwide. It is estimated that the incidence and mortality rate of the CRC will increase by 77% and 80% by 2030, respectively [7].

The incidence and mortality rate of this cancer varies in different regions [11,12], which is more common in developing countries than in the rest of the world [13]. Fortunately, its mortality rate is declining in many western countries [7].

Cancer is also the third leading cause of death in Iran, so that the incidence of CRC has increased during the past 25 years in Iran especially among younger people [14,15].

Various risk factors have been reported for colorectal cancer, including aged more than 50 years, family history, nutrition patterns, obesity, inactivity, and cigarette smoking. However, the main cause of it has not been accurately known [9,16-19].

The survival rate of the CRC is reported 5 years after diagnosis [13], which is highly dependent on the time of diagnosis, so secondary prevention, which is the early
diagnosis of cancer, is important [6,14]. The CRC is suitable for screening because it is a challenging health problem and there are some tests that can diagnose it earlier [20]. Initial and necessary measures for screening colorectal cancer often include training and advice for screening tests [21]. Regular screening is one of the best and most valuable early detection methods in the CRC [22-26].

Fecal Occult Blood Test (FOBT) and colonoscopy are the most commonly used tests for colorectal cancer screening [4]. One of the reasons for the low CRC screening rate is the lack of participation in these programs [27]. In addition, standard educational materials for promoting CRC screening have also been unfortunately unsuccessful [28]. Three major categories of screening agents have been reported in various sources including: 1) demographic characteristics such as race, ethnicity, level of education and age; 2) psychological effects such as knowledge, risk perception and health behaviors, and 3) health system factors such as health insurance coverage, physician advice and the usual source of health care.

Also, studies have shown that people who are involved in unhealthy behaviors, such as smoking and physical inactivity, are less likely to use screening tests recommended for cancers [29].

In a study entitled "Factors Associated with the Fecal Occult Blood Testing for Colorectal Cancer Screening", the results showed that in the referred group, the majority of the subjects were married with higher education and appropriate economic status [15]. There are some systematic reviews entitled "Weight loss as a predictor of cancer in primary care", "A systematic review examining quality of life following pelvic evisceration for locally advanced and recurrent rectal cancer" and "How useful is thrombocytosis in predicting an underlying cancer in primary care" focusing on the CRC [30-32].

Considering the importance of the CRC and the lack of comprehensive systematic reviews in this field led us to review the predictive factors for participating in the CRC screening programs. Indeed, no study included all related factors for prediction of participation in the CRC screening, so that the novelty of this paper is due to its comprehensiveness.

MATERIALS AND METHODS

Search strategy

International databases including PubMed, ISI and Scopus were considered for search of English articles from year 2000 to 30 December, 2018. Thirty-one published articles were finally entered into the study. Keywords were "colorectal cancer", "colorectal neoplasm", "predictor", "screening", "FOBT", "Fecal Immunochemical Test (FIT)", "education", "smoking", "obesity" or a combination of them in the title/abstracts.

For example search strategy in PubMed database was as following with 15079 studies:

Selection of articles

After collection of articles of interest, references imported to Endnote software and removed duplicate titles. Then, after browsing titles, studies with irrelevant purpose were removed, and then the remaining studies assessed by two independent investigators.

The selected studies were performed on humans and published in English. The selection process using Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement can be seen in Figure 1.

Figure 1: Selection process using PRISMA

Data extraction

Information dealing with the selected articles (the author's last name, year of publication, study design, sample size and the results of each article were taken by two independent investigators.

The differences observed in this process corrected by a third investigator who was independent with the two previous investigators.

FINDINGS

There were 367248 subjects reviewed in this systematic review of 31 published articles consisted of two cohorts, one quasi-experimental, one mixed method, three randomized trial and twenty-six cross-sectional designs. The summary of the articles included in this review is available in the Table 1.

**DISCUSSION**

Various risk factors have been reported for colorectal cancer, including age more than 50 years, familial history, nutrition patterns, obesity, inactivity, and cigarette smoking. However, the main cause of it has not been accurately known [9]. The survival rate of the CRC is highly dependent on the time of diagnosis, so secondary prevention, which is the early diagnosis of cancer using screening programs, is important [6,15]. This study aimed to review the predictive factors for participation in colorectal cancer screening.

A study by Wee et al., on the factors associated with the CRC screening from the United States families, found that half of the subjects reported having a history of the CRC screening in the last 10 years. After adjusting age, gender, body mass index, access to health care and national territory, Spaniards were less likely to participate in screening tests than whites and people with less education. However, non-whites and people with less education reported fewer counseling from health care providers to take the screening tests. Of the respondents who did not participate in the FOBT, the most reason was the lack of knowledge, but pain, discomfort and not counseling by a physician were effective. The results also
showed that the low prevalence of the CRC screening was due to low awareness and inadequate counseling by health providers about the low screening acceptance of the patients [64].

A review study in the United States was conducted by Beydoun et al. and reviewed the predominant predictive factors for colorectal cancer screening among high-risk individuals (over 50 years of age). The results showed that the predominant predictive factors for the CRC screening included elderly, male gender, being married, high education level, high income, white race, non-Hispanic ethnicity, history of smoking, history of chronic disease, family history of colorectal cancer, common source care, physician's advice, use of other preventive health services and health insurance coverage. More psychosocial predictors were examined based on the health belief model. The most prominent were the perceived barriers for the CRC screening. Evidence has shown that the CRC screening is a complex behavior with a number of factors including individual characteristics, health insurance coverage, and the relationship between physician and patient [65].

A study was done by Yong et al. on the CRC screening: Obstacles to the FOBT and colonoscopy in Singapore using household survey and home samples. The subjects were aware of colorectal cancer screening methods and interviewed about the screening barriers. Most of the responses to not participate in the CRC screening were having no symptoms for participating in the FOBT, discomfort, having no family history of the CRC, lack of time and lack of reminders or advice. The results showed that the lack of knowledge especially the misconceptions about the lack of signs and health, were identified as the main obstacle to participate in screening [66,67].

**CONCLUSION**

According to the findings, several factor are involved to participate people in CRC screening including belief, thinking style, attitude, knowledge, accessibility to screening facilities and geographic variation, participation in the first round of screening with post-education issues, elderly, fecal disgust, race, low socioeconomic status especially income, being married and female, trust to physician and kindly contact of health providers, counselling centres and psychosocial disorders, in such a way that these factors are effective predictors in the participation of people in the CRC screening programs. Authorities should focus on these factors to promote the health of people by participation in the CRC screening programs.

**AUTHORS’ CONTRIBUTION**

All the authors have contributed towards conducting the paper and preparation of the manuscript and they all have approved the latest version of the article.

**ETHICAL CONSIDERATIONS**

Ethical issues observed totally by all authors of this study such as plagiarism, double publication and data fabrication.

**CONFLICT OF INTEREST**

The authors declare that there is no conflict of interest regarding the publication of this article.
